

Java Script

Name : Betel Amare

Id : CTC-6184-26

A short explanation what I have learnt from the recommended website.

Java Script is one of the most important programming language that one programmer need to know next to HTML and CSS. It is a high level interpreted programming language and also it makes your web page interactive and dynamic. Java script was created in **1995** by American programmer called **Berdan Eich**.

Java script can accept both single and double quotes. which means you can write “hello” or ‘hello’.

Java script is a case sensitive programming language, meaning “betel amare” and “Betel Amare” are completely different .

Java script code is inserted between **<script>** and **</script >** tags in HTML code.

Java script in body:-script interpretation slows down the display so placing scripts at the bottom of the <body> element improves speed.

Java script assigning variables let x,y,z

X=5	x and y are literals and literals are numbers and strings
Y=6	example :-numbers are any random numbers with no quotation an
Z=x + y =11	d strings are words with quotation(“hello”).

A java script name must begin with these three:-

- Letters (A-Z)
- Dollar sign (\$)
- Under score (_)

Java script has 3 ways to declare variables . These are

- **Var**- oldest way (old browsers)
- **Let**- variables that change
- **Cons**- variables that don't change

Constant key word was introduced in 2015

Java script has 4 output methods . these are:-

1. **Inner.html()** It replace the entire page after the page reloads .
2. **Document .write()**to write text or HTML code directly to the browser window
3. **alert()** For notifications and alerts.
4. **console.log()** Logs messages straight to the browser console(usually by pressing F12)

NB: we print the current page directly by using java script button.

Java script conditions

The if statement

Runs a block of code **only if** the specified condition inside the parentheses evaluates to `true`.

The else statement

Use the else statement to specify a block of code to be executed if the condition is false.

Functions allow you to write code once, give it name , and run it multiple times

Why Use Functions?

- **Code Reusability:** Write once, use everywhere.
- **Organization:** Break large programs into smaller, manageable pieces.
- **Easy Maintenance:** Fix a bug in one function, and it updates everywhere.

Key words:

Document. getElementById () selects and specifies HTML elements by their id

Add Event Listener () listens specific user action (just like" click").

Text content modifies the text inside HTML element quickly and dynamically.

Class list. Toggle () dynamically adds or removes a css class to switch styles instantly
